Service Based Generation of Latex Graphical Dependencies

Pavol Buzák, Katarína Žáková and Zoltán Janík

***Abstract*—**As it is known, LaTeX enables typesetting of medium-to-large technical or scientific documents that includes not only text and mathematical expressions but also graphical objects. There exist several packages for generation LaTeX graphics that are based on PostScript, PGF ("Portable Graphics Format"), Metapost, etc. Preparation of LaTeX pictures using any of these technologies require to learn related procedure steps, new syntax and relevant functions. It can be reasonably time consuming and not all scientists and users have enough time to do it.

The paper presents a web service that enables to automate generation of pictures that contain graphical dependencies of variables on the base of uploaded numerical values. Considering properties of several packages we decided to use two of them: Pgfplots and Gnuplottex based on Gnuplot. Both are wide spread, their syntax is easy to learn and commands for graphics generation can be written directly in the LaTeX source code.

The presented web service is developed using JSON-RPC. The service and the complementary web application enable to take into account user's preferences regarding layout and appearance of resulting pictures and facilitate the picture production.

***Keywords*—**computer-aided design, web service, JSON-RPC, Latex.

I. Introduction

It is said that "it's always better to see once rather than to hear twice". Another Chinese proverb says that "a picture's meaning can express ten thousand words" [5]. The meaning of both sayings is more or less the same and it can be related not only to common everyday life but also to technical education. Measured experimental results or results from simulations are very often documented by means of graphical dependencies. They enable to evaluate the quality of achieved outputs much faster than e.g. tables or verbal description. Pictures with charts can be generated by various software applications, e.g. Matlab, Maple, Mathematica, Excel, Maxima, etc. We could list many of them. However, it is usually not so common that such pictures are generated directly in the word processor. LaTeX can be considerd as one of such examples. This paper aims to show how this procedure can be done automatically and more user-friendly. In order to achieve this aim, we have designed a new web service for this purpose.

Different authors give different definitions to Web Services. Leidago Noabeb [7] introduces that "A Web service basically is a collection of open protocols that is used to exchange data between applications. The use of open protocols enables Web services to be platform independent. Software applications that are written in different programming languages and that run on different platforms can use Web services to exchange data over computer networks such as the Internet." He also states that since "different applications are written in different programming languages, they often cannot communicate with each other. A Web service enables this communication by using a combination of open protocols and standards, chiefly XML, SOAP and WSDL." In spite of the fact that there already exist other open technologies for building service-based applications, Noabeb's definition describes all main features of the web service.

II. LaTeX and Graphics

As it is written on LaTeX web site (http://latex-project.org/intro.html), LaTeX is a document preparation system for high-quality typesetting. It is most commonly used for medium-to-large technical or scientific documents but it can be used for almost any form of publishing. However, it is to say that it is not a word processor, but it is a markup-based typesetting language.

LaTeX contains features mainly for typesetting journal articles, technical reports, books, and slide presentations. It is able to take control over large documents containing sectioning, cross-references, tables and figures. It enables to typeset complex mathematical formulas, generate bibliographies and indexes, etc. In addition, it can be also used to produce graphical objects.

LaTeX can be used together with PostScript (on which PDF is based). LaTeX's mathematical capability, its paragraph building, its hyphenation, and its programmable extensibility can cooperate with the graphical flexibility and font-handling capabilities of PostScript and PDF [1].

PostScript is object-oriented computer language enabling to describe the graphical appearance of a printed page. It was developed by Adobe Systems Incorporated. Its main advantage is that it is independent on device on which the document is printed. PostScript can be considered as a standard for

desktop publishing. It is supported by the most of high-resolution printers to produce camera-ready copy. There exist several packages for generation LaTeX graphics that are based on PostScript:

- PSTricks, where the necessary PostScript code can be generated by TeX macros defined in the package. It is often used as a base for other LaTeX libraries.
- Pst-plot utilizes PSTricks macros for creation of vector graphics.
- Bardiag, Bchart – both of these packages are already deprecated. They can be used only for producing bar graphs.

Another possibility to generate LaTeX Graphics is offered by command line based Gnuplot program that is a portable command-line driven graphing utility for various platforms.

The set of programs PGF/TikZ also enables the creation of high quality drawings for LaTex. PGF is the basic layer, providing a set of basic commands for producing graphics, and TikZ is the frontend layer with a special syntax, making the use of PGF easier.

PGFPlots is a package that is based on the combination of programs PGF/TikZ. It was directly developed to generate graphs for LaTeX.

Package Matlab2Tikz converts graphs from Matlab to LaTeX using PGFPlots library.

Metapost programming language enables to create vector graphics. It generates figures for technical documents where some aspects of a picture may be controlled by mathematical or geometrical constraints that are best expressed symbolically [2].

Similarly Asymptote is also language for generating vector graphics. However, it requires an external program for compilation of a resulting output document.

Finally, R language can be mentioned. It is a free software environment for statistical computing and graphics.

A brief comparison of all mentioned projects is listed in Table 1. Since we usually use MikTeX distribution of LaTeX, we were interested in the fact, whether the considered package is included in MikTex repository or not. Subsequently, it is interesting to know whether the package includes functions for graphics generation directly. Since the final documentation is very often prepared in PDF format, it is important to know how demanding the preparation of PDF document is - whether it can be compiled directly from the LaTeX source code or whether the source code needs to be compiled to a postscript file first and only then it can be converted from the postscript file to the PDF format.

Considering all properties of mentioned packages, we decided to focus on two solutions: Pgfplots and Gnuplottex based on Gnuplot. Both of them are wide-spread, their syntax

is easy to learn and commands for graphics generation can be written directly in the LaTeX source code. Pgfplots enables to produce PDF format of document without a need to use external programs (using pdflatex). Gnuplottex needs to prepare Gnuplot code that can be compiled to PDF format directly. Both of these packages were implemented into the presented solution.

III. Remote Procedure Call

Remote Procedure Call (RPC) is a protocol for requesting a service from a program located in a remote computer through network without having to understand the under layer network technologies [8].

RPC uses the client/server model. The requesting program is a client and the service-providing program is the server. First, the client sends a call message that includes the procedure parameters to the server process (Fig.1). After that, the caller process waits for a reply message. Next, a process on the server side, which is idle until the arrival of the call message, extracts the procedure parameters, computes the results, and sends a reply message. The server waits for the next call message. Finally, the caller's process receives the reply message, extracts the results of the procedure, and the caller resumes execution [8]. The server and the client application logic are kept independently, thus multiple clients may be written using the same server API.

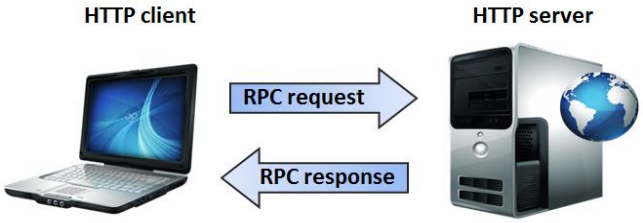

Fig. 1 Remote Procedure Call communication

According to the format of the sent messages, it is possible to consider XML-RPC or JSON-RPC. We decided to use JSON-RPC because JSON is not as verbose as XML and for humans, it is faster to write JSON. Despite that XML is used to describe structured data, it doesn't include arrays, while JSON does.

IV. Realization

As it was already mentioned, the developed service allows to process requests in JSON-RPC. The server provides responses according to the used RPC request protocol.

A. Web Service Request

For API implementation JSON-RPC 2.0 specification was used [6]. In such a case, the request object can contain three properties:

- method - a string containing the name of the method to be invoked;
- params - an array of objects to pass as arguments to the method. This property can be omitted;
- id - the request ID that can be of any type. It is used to match the response with the request that it is replying to.

The created web service implements only single method – generate. Its task is to produce LaTeX code that is able to generate the picture presenting graphical dependencies with values specified in the input file.

Afterwards the generated code can be included to the LaTeX document and compiled to the final PS or PDF file. The created service enables to produce not only LaTeX code with the required graphics but also its PNG or PDF equivalent.

Fig.2 illustrates an example of the JSON-RPC request. As one can see, the request contains several parameters. Parameter user_input_data enables to specify input file with data that should be visualised by means of graphical dependence. In the picture, one or more graphical dependences can be presented. Parameter user_template allows to choose a LaTeX template that forms the environment for graphics included to the document source code. APIkey parameter specifies the alphanumerical code of the person that is allowed to use the presented service. Parameter pdf defines the format of the desired output. In similar way, one can define PNG or LaTeX format. The rest of parameters describe the graphical presentation and graphical layout of the resulting figure.

```
{"jsonrpc":"2.0",
 "method":"generate",
  "params":[{"APIkey":"xxxxx",
             "graph_type":0,
             "user_template":"pgfplots.tex",
             "user_input_data":"input.dat",
             "font_size":2,
             "pdf":1,
             "show_grid":1,"legend_show":1,"x_tics":1,
             "x_min":-10,"x_max":10,"y_min":-1.2,"y_max":1.2,
             "width":"15cm","legend_position":"outer north east",
             "x_label_pos_x":1.05,"x_label_pos_y":0.5,
             "y_label_pos_x":0.5,"y_label_pos_y":1.1,
             "lines":[{"file_index_x":0,"file_index_y":1,
                       "legend":"sinus"},
                      {"file_index_x":2,"file_index_y":3,
                       "legend":"kosinus",
                       "line_color":"green"}]}],
  "id":1}
```

Fig. 2 Example of JSON-RPC request

In Fig.3, one can see an example of LaTeX template that was used in the previous JSON-RPC request. As it is possible to see, the template is a standard LaTeX document that starts with the import of necessary packages and continues with setting of page style. The body of the document is created by the graphics that was completed using the presented service.

B. Web Service Response

The response object also has three properties:

- result - the object that was returned by the invoked method;
- error - an error object if there was an error invoking the method;
- id - the same id as the corresponding request id.

It is to say that in the JSON-RPC 2.0 specification, each response object can contain only one of the first two properties (either "result" or "error").

ISBN: 978-1-61804-247-7

```
\documentclass{article}

\usepackage{pgfplots}
\usepackage{fullpage}

\pagestyle{empty}
\begin{document}

%EXPORT_BEGIN%
\begin{tikzpicture}
  \begin{axis}[axis x line=center, axis y line=center,
    xlabel={$x$}, ylabel={$y$},
    xlabel style={at={(1.05, 0.5)}},
    ylabel style={at={(0.5, 1.1)}},
    xmin=-10, xmax=10, ymin=-1.2, ymax=1.2,
    width=15cm, height=5cm,
    every axis/.append style={font=\small},
    xtick={-10,-9,...,10},
    grid, legend pos=outer north east]

  \addplot[smooth, line width=1pt, color=red, style=solid]
          table[x index=0, y index=1] {input.dat};
  \addplot[smooth, line width=1pt, color=green, style=solid]
          table[x index=2, y index=3] {input.dat};
  \legend{$sinus$, $kosinus$}

  \end{axis}
\end{tikzpicture}
%EXPORT_END%

\end{document}
```

Fig. 3 LaTex template specified in JSON-RPC request (pgfplots.tex)

The successfully realized response to the request from the previous example is shown in Fig.4.

The response returns the URL address of the generated PDF file. In the case when the LaTeX code was requested, the result property contains the code that can be seen in Fig.3 between strings EXPORT_BEGIN and EXPORT_END.

If the request fails, the response will contain the error property as it is demonstrated e.g. in Fig.5.

```
{"jsonrpc":"2.0",
 "result":"http://www.example.sk/latex/tmp/139357/pgfplots.pdf",
 "id":1}
```

Fig. 4 Example of successful JSON-RPC response

```
{"jsonrpc":"2.0",
 "error":{"code":1,"message":"Wrong API key."},
 "id":1}
```

Fig. 5 Example of failure JSON-RPC response

To extend the presented web service, we also developed the online web application. It enables to set all graph parameters via online form. Then, after uploading the file containing numerical data that should be visualized as graphical dependence/dependencies in the picture, choosing the preferred library and the output format, the generation of the required result can start. The created graphical user interface offers a comfortable way of the picture production.

V. Conclusion

The paper presents a service that can facilitate preparation of scientific documents written in LaTeX - the documents that include graphical dependencies of measured or calculated values. The required LaTeX code that describes the picture is generated automatically using one of two available LaTeX packages: Pgfplots and Gnuplottex. The introduced tool enables to take into account user's preferences regarding the layout and the appearance of produced pictures. In this way, it offers extension to the LaTeX usability for unskilled users, too. It can also be used by scientists, teachers and students during writing their final thesis.
